What's the RSA

Prime factorization of large number is difficult. This is because there is no other way to find prime factors except by round-robin.

Therefore, even if one tries to factorize a large number using a computer, it will take an enormous amount of time.

The RSA cipher uses this mechanism.

This is named after the three inventors, R.L.Rivest, A.Shamir, and L.Adleman.

A type of algorithm for public key cryptography

RSA cipher is a type of algorithm for public key cryptography.

Public key cryptography is an encryption scheme in which the encryption key and decryption key are separate.

With RSA, the plaintext, key, and ciphertext are numbers.

Denote the ciphertext as C , plaintext as P .

Encryption by RSA

$$C = P^E \bmod N \quad (1)$$

$\{E, N\}$ is the public key.

RSA decryption

$$P = C^D \bmod N \quad (2)$$

$\{D, N\}$ is the private key.

Make keys

How to prepare the E, D, N ?

- ① N is obtained.
- ② L is obtained. (L appears only when making the keys.)
- ③ E is obtained.
- ④ D is obtained.

N is obtained
